

*fastRise*<sup>™</sup>

## Processing Guide

August 2017

**Disclaimer:**

This process guide is provided to users *fastRise*<sup>™</sup> to assist in gaining an understanding of these materials and to quickly establish processes for PCB fabrication. It is assumed that the users will have a technical understanding and experience in the processes, equipment and standards related to PCB fabrication. The user will likely need to make adjustments to account for specific requirements and their production processes.

The following process recommendations are based on testing and production processes at several circuit board facilities. Each facility will have different product designs, equipment, or methods that will require modifications to these recommendations. For example, drilling parameters, routing parameters, and artwork compensation can vary dependent on circuit board thickness, design, processes, and equipment.

Adjustments should be based on the experience of each facility. Please contact your Taconic representative if assistance is required.

# GENERAL INFORMATION

---

## Overview

*fastRise*<sup>™</sup> prepreg is designed for applications where low loss or high operating temperature is required. *fastRise*<sup>™</sup> utilizes a high loading of ceramic for low electrical loss and dimensional stability, a high performance thermoset resin as a bonding agent, and a small amount of PTFE. Each ply of *fastRise*<sup>™</sup> is comprised of three layers; a pliable highly ceramic loaded PTFE film with a thermosetting adhesive resin on the top and bottom:

It is important to understand that the different *fastRise*<sup>™</sup> part numbers have been optimized for different applications; using the correct *fastRise*<sup>™</sup> part number for each design can greatly ease fabrication and improve quality. *fastRise*<sup>™</sup> can be roughly broken into four families (standard, specialty, S, and 7) in which variants of the center film and/or resin are used (details are discussed below).

More detailed information regarding specific *fastRise*<sup>™</sup> part number properties can be found on the data sheet(s).

## *fastRise*<sup>™</sup> Standard Prepregs

The standard *fastRise*<sup>™</sup> family use a ceramic loaded PTFE film and are recommended for the majority of applications. This family provides a very versatile material with forgiving processing.

## *fastRise*<sup>™</sup> Specialty Prepregs

The specialty *fastRise*<sup>™</sup> family uses a pure PTFE film which enables thinner dielectric thicknesses. Although this product is used daily in production applications with excellent results, it should be noted that it is less forgiving in processing and additional process development may be required. The primary difficulty is a result of drill smear from the pure PTFE film which can be resolved. Additionally, the pure PTFE film can make it difficult to obtain laser vias comparable to industry norms.

# fastRise™ S Prepregs

The *fastRise™ S* family employs much of the same nanomaterial technology utilized in EZ-IO. *fastRise™ S* prepregs maintain the performance gains of EZ-IO nanomaterials while providing simplified and reduced processing costs. The *fastRise™ S* family will also grant improved hole quality for both mechanical and laser drilled vias. Such prepregs include *fastRise™ S* part numbers FR28-0040-50S and FR27-0050-40S, though others may also be made available.

*fastRise S*  
(Nanomaterial)

*fastRise*  
(Standard)

Notice the difference in the film particle sizes between the FR27-0050-40S and standard FR27-0050-40

# fastRise™ 7 Prepreg

*fastRise™ 7* is a high Dk (7.45 at 10 GHz) prepreg designed for use with other high Dk laminates. It consists of a fiberglass reinforced PTFE/ceramic film with a modified *fastRise™* resin coated on each side. There is only one *fastRise™ 7* part number with a nominal thickness of 0.0055" (140µm). Applications requiring fill of copper greater than 1 oz should be discussed with Taconic technical service. Processing of *fastRise™ 7* is similar to other *fastRise™* part numbers, exceptions are noted in this guide where applicable.

# STORAGE

---

Store the material in a cool dry area away from direct sunlight and high humidity, avoiding material contamination. *fastRise™* is certified to meet all requirements as agreed upon between the user and supplier for a given shelf life as defined by the storage conditions below.

## Storage Conditions

Condition 1 (i.e. refrigeration): <4.5°C (40°F)

Condition 2 (i.e. room temp): <23°C (73°F), Relative Humidity <50%

When removing *fastRise™* prepreg from refrigeration, it should be allowed to acclimate to room temperature in the sealed bag. This will reduce the chance of moisture condensation on the prepreg and will also provide a more consistent start temperature for the lamination process. Bags should be resealed when not in use.

## Shelf Life

If material is stored under Condition 1 above, a shelf life of 180 days after receipt of shipment will apply. If material is stored under Condition 2 above, a shelf life of 90 days after receipt of shipment will apply. Taconic will not ship *fastRise™* material with less than 90 days of remaining shelf life. Packaging will default to indicate shelf life based on storage Condition 2 unless we are notified that Condition 1 applies. In the event that prepreg expires, please contact your Taconic technical sales person for assistance to coordinate re-testing the expired prepreg.

# HANDLING

---

*fastRise™* prepreg is supplied between two release sheets. The surface of *fastRise™* may be tacky (especially for freshly manufactured material). Although it is recommended to allow refrigerated *fastRise™* prepreps to acclimate prior to opening a sealed bag, in some cases it may be advantageous to use the prepreg while it is cool\* which will reduce the tackiness of the material and make handling easier.

*\*do not allow condensation to form on the prepreg*

**Note:** The *fastRise™* 7 resin exhibits a high degree of tackiness and should always be handled at cooler temperatures to prevent contamination or other handling damage.

# INNER LAYER PREPARATION

---

## Laminate Preparation

*fastRise™* will bond well to most other materials. Inner-layers should be clean and dry before bonding. Oxide treatments of copper surfaces are recommended.

## Flow Patterns / Thieving

Solid copper boarders with small alternating “star burst” vent lines are ideal. Interlocking thieving patterns, offset diamonds, honeycombs, or other patterns which inhibit resin flow channels are also acceptable. Interlocking “star burst” flow patterns or other patterns which may promote resin flow channel formation should be avoided.

# LAMINATION

---

*Excessive resin flow should be avoided as it can cause flow channels or other undesirable conditions.*

## Quick Start

*The following chart is provided as a general starting point for lamination recipe development. The later sections provide substantially more detail allowing recipes to be optimized for specific applications.*

	Foil Lamination* / Low flow	Standard	High Flow / 30+ Layers
<b>Vacuum</b>	Full vacuum is recommended through entire cycle		
<b>Vacuum Delay</b>	Hold vacuum 10-20 minutes before applying heat or pressure		
<b>Heating Rate</b>	3 – 8 °F/min (2 – 4 °C/min)		
<b>Critical Range</b>	176°F – 302°F (80°C – 150°C)		
<b>Pressure</b>	100 – 200 psi	200 – 350 psi	350 – 550 psi
<b>Cure Temp / Time (measured at bondline)</b>	420 – 480 °F for 60 – 120 minutes (215 – 250 °C for 60 – 120 minutes)		
<b>Cooling Rate</b>	Less than 6°F/min (3°C/min)		
<b>Breakdown</b>	Breakdown or transfer to cold press when bondline is less than 200 °F (95°C)		

*\*Please see the section on Foil Lamination which covers additional process parameters*

## Padding and Conformance Materials

Press padding (outside separator plates) is recommended. Use of conformance materials such as Taconic TacPad, PTFE skive film, clutch lamination, or others are often helpful to balance pressure variations induced from circuits.

## Pressure

*Excessive pressure should be avoided; it can distort circuit patterns, induce resin/filler separation, or create flow channels.*

Full pressure should be achieved before the *fastRise™* reaches 250°F (120°C). *fastRise™* resin flow has been shown to be directly proportional to lamination pressure. Pressure can be used to control flow so that high-flowing *fastRise™* part numbers can potentially act as no-flows. Conversely, low-flowing part numbers can achieve additional flow with increased pressure.

For example, FR27-0035-66 resin flow can be approximated with the following equation:

$$\text{Flow \%} = \text{Pressure} \times 0.0002 \quad [\text{psi}]$$

Data has shown that lower lamination pressures are linked to decreased grain-direction scale variation between panels (see *Pressure Effects on Scaling* below). This effect was not observed in the fill-direction. Although low pressures can be used to reduce grain-direction scale variation, it is advised to modify heating rates before reducing the pressures because heating rates have a larger impact on scale variation and the risk of inadequate pressure is avoided.

Many fabricators find that a lamination pressure of 200-350 psi is effective for the majority of products. In the event that high flow is required (e.g. heavy copper, via filling, etc.), some fabricators increase lamination pressure to 350-550 psi. Likewise, for low-flow applications (e.g. cavities, foil lamination, etc.) pressure ranges of 100-200 psi are often advantageous.

**Note:** The *fastRise™ 7* resin is a lower flowing resin and should be laminated using the highest possible pressure (500+ psi). Care should also be taken during the design phase to minimize low pressure areas in the board and coupons to prevent lamination voids.

## Low flow applications

Where limited or no resin flow is required, there are low resin flow formats of the *fastRise™* and the engineer should consider using these types along with exploring how to manage the flow level with pressure and time in the low viscosity window, with the specific design of PCB.

It is strongly recommended that suitable conformal press materials are used as well as employing methods for damming the resin flow in cut-outs or cavities.

Where cut-outs are made in the *fastRise™*, damming methods help with limited registration, restricted clearance to vias near the cavity, and gathering at the cut path when using mechanical processes. Although the minimum pressure should be used, pressure must be adequate to achieve adhesive contact surrounding the cutout area. Extending time in the low viscosity window may be helpful.

# Temperature

## Resin Flow Window / Critical Range

*fastRise™* resin gels and flows between 176°F - 302°F (80C – 150°C) and reaches its lowest viscosity between 215°F – 260°F (100°C – 125°C). Extending the time in which the resin is at its lowest viscosity can improve flow and may be advantageous in hard to fill applications (e.g. heavy copper, embedded component cavities, via filling, etc.). Lengthening the time in this low viscosity window is accomplished by reducing the heating rate or by adding a dwell of up to 1 hour at 250°F (120°C).

**Note:** Due to its lower flow rate, *fastRise™ 7* laminations should always include a 30-60 minute dwell at 250°F (120°C) against anything other than ½ oz copper (or where low pressure areas may exist).

## Heating Rate

A cold start of the press is desirable. Typical *fastRise™* heating rates are 3-8°F/min (2-4°C/min) and rates of 3-10°F/min (2-5°C/min) have been successful. In difficult to fill applications such as heavy copper (>1oz.), via filling, using *fastRise™ 7*, etc. or in high layer count boards, a slow heating rate should be used. It is strongly recommended that low heating rates be used if the process is to accommodate tight registration requirements or high layer counts. Data has shown that lower heating rates can provide substantial improvements in registration repeatability (see *Heating Rate Effects on Scaling* below)

## Curing

Curing begins at 395°F (200°C) and *fastRise*<sup>™</sup> curing processes are usually designed to hold the bondline between 420°F – 450°F (215°C – 230°C) for a minimum of 1 hour. Curing temperatures of up to 480°F (250°C) can be used and the elevated temperatures will achieve performance gains while lower temperatures have also been successful in hybrid lamination cycles.

Taconic has observed that higher lamination temperatures combined with a 2 hour dwell can lower Z-axis CTE values by more than 30%. High-reliability applications often use a 2 hour cure at the elevated temperatures. The reduction in Z axis CTE is related to the resin content of the *fastRise*<sup>™</sup> part number and will vary by *fastRise*<sup>™</sup> part number.

Elevated curing temperatures have also been shown to improve peel strengths. For this reason, it is strongly recommended that foil laminations use a cure temperature of at least 450°F (230°C).

Hybrid laminations have successfully been accomplished by curing at 395°F (200°C) for 3 hours. Taconic advises caution as this is the minimum possible cure temperature and adhesion may be reduced.

## Cooling

A slow cool is necessary to avoid any issues associated with delamination. The hot press should be cooled below 200°F (95°C) before transferring to a cold press. In situations where mismatched CTE's may induce delamination or where warping may be an issue, slower cooling rates may provide better results.

## Foil Lamination

### *fastRise*<sup>™</sup> Selection

FR27-0040-43F and FR25-0021-45F were specifically designed for foil laminations and tend to provide superior surface quality and aesthetics. FR27-0040-43F is preferred due to the increased chances of drill smear with FR25-0021-45F. Other *fastRise*<sup>™</sup> part numbers will also work with foil lamination, but additional process development may be required. Lower flowing part numbers typically yield better results.

### Recommended Foils

TWS or TW foils from Circuit Foils is ideal. Other copper foils with sufficient dendrite tooth structure may also be acceptable.

### Pressure

Foil lamination requires minimal pressure. 100-200 PSI should be adequate and higher pressures may be used to fill copper that is plated to 1-2 oz. If the surface appearance shows signs of excessive flow or flow channels, the pressure should be reduced. Pressure has a little to no impact on peel strength. Cure temperature is much more effective at improving bond strengths.

## Temperature

Slower heating rates are recommended for foil laminations and an added 60 minute dwell at 225°F (110°C) may also be advantageous to allow the resin to flow uniformly without flow channels. When heating from 225° (110°C) to 450°F (230°C), much lower heating rates of 3-5°F/min (2-3°C/min) should be used. A cure temperature of 450°F (230°C) for a minimum of 1 hour should be used for foil laminations. Peel strengths increase with elevated cure temperatures and extended cure times. Cooling rates should not exceed 6°F/min (3°C/min) until bondline is less than 200°F (95°C).

## Foil Lamination Surface Quality

Excessive resin flow can cause flow channels which may be visible on the foil surface after lamination.

If the adhesion is good in some areas but delamination is found in other areas, it is likely the result of thermal shear stresses and there are several steps which can be taken. Cooling should never be done by transferring the laminates from a hot press to a cold press. Cooling rates of 2-4°F/min (1-2°C/min) or lower are ideal. An aluminum sheet and/or conformal padding (e.g. Taconic TacPad, skive PTFE, PacoPlus, etc.) placed between the panel and the steel plate will help reduce transferred shear stress. Press padding, such as PacoPad will also help.

Several fabricators have found clutch laminations helpful in which a layer of higher flowing prepreg (e.g. FR4, acrylic, polyimide) is placed between release sheets (e.g. PTFE film, foil release, PVDF film) that are then placed against the part during lamination. The higher flowing prepreg will provide hydrostatic pressure as well as offset thermal stresses.

## Additional Notes

### Cavity Applications

All *fastRise™* part numbers can be successfully used in cavity applications. Prepreg cutbacks are often 0.005" - 0.020" (0.1 – 0.5 mm), but results can vary widely based on the board design, processing, and between *fastRise™* part numbers. Low flowing part numbers, such as FR27-0040-43F and FR25-0021-

45F, are often ideal for processing without a plug or dam to restrain resin flow. Other part numbers will benefit from the use of a plug or dam to contain resin flow from depositing within the cavity area. Since resin flow is proportional to lamination pressure, pressures as low as 75-150 psi are sometimes used to prevent resin flow into the cavity area. Again, results can be greatly impacted by design, process, or differences between part numbers. Taconic Technical Service is available for assistance.

### Poor Pressure Distribution

Constructions containing very low pressure areas with stacked regions of little or no copper between layers (e.g. coupons, ground clearances, fiducials, etc.) may require special considerations to achieve ideal bonding. Resin from the higher flowing *fastRise™* part numbers combined with higher pressures will fill the low pressure areas to balance the pressure. Although the low flow *fastRise™* may be capable, caution is advised to ensure that adequate resin flow and resin volume are present to avoid poor adhesion and resin starvation. Copper distribution should be as balanced as possible especially with thicker or plated circuits.

### Multiple Ply Constructions

Resin flow can increase dramatically if multiple plies of *fastRise™* are used against each other. If high-flow is not desired, pressure should be reduced to approximately 25%-50% to prevent excess resin flow, resin separation, or formation of flow channels.

### Encapsulating the conductor pattern

Although *fastRise™* film is not porous, it is flexible and will conform to circuit patterns. The film can have an elongation of 30-300% and will fill circuit patterns as long as there is sufficient resin to flow within the areas.

The flexible *fastRise™* film has conformed so that the cavity is completely filled

# DRILLING

*In most cases, the laminate cores will dictate drilling parameters. The following information is provided as a general suggested starting point where fastRise is the primary material.*

*Contact Taconic technical service for Taconic laminate processing guides.*

## Quick Start

	Imperial units	SI units
<b>Entry Material</b>	Phenolic (0.010" – 0.024")	Phenolic (0.25mm - 0.6mm)
<b>Backer Material</b>	Rigid Phenolic, Slickback, or comparable	
<b>Cutting Speed (surface speed)</b>	100 SFM	30.5 MPM
<b>Chip Load</b>	0.0010 in.	25 μm
<b>Dwell</b>	0-1000 ms (increase dwell time as speed and chip load deviate from above recommendations)	

## Drill Bits

Sharp drill bits are critical to any PTFE drilling; new drill bits should always be used. Undercut drill bits are recommended, but past studies have shown that some drill bit brands may obtain better results using their standard drill bits.

## Chip Load

A chip load of 1.0 mil (25  $\mu\text{m}$ ) is common when *fastRise*<sup>™</sup> is paired with ceramic/PTFE laminates. Increasing the chip load to 1.25 mils (30  $\mu\text{m}$ ) may provide acceptable hole quality and improved productivity.

## Cutting Speed

Drill speeds of 100 SFM (30.5 m/min) or less will usually eliminate drill smear if it is present. The slower speeds allow generated heat to dissipate before smearing PTFE. Drill speed can be increased due to equipment limitations, but added dwell times may become more important.

## Dwell Time

If smear is present and ideal cutting speeds cannot be obtained, a 250ms dwell is recommended for initial process setup in order to cool the drill bit between holes. Past Taconic studies have shown that hole-wall quality in PTFE materials may improve as dwell times are increased to as much as 1000ms.

## Peck Drilling

Peck drilling should be avoided where possible; it has been shown to increase drill bit wear as well as increase process time. Peck drilling may be required in some situations (e.g. bird nesting, hole plugging, chip extraction on thick panels, breaking thin drill bits, etc.).

If traditional peck drilling is not used, hole-wall quality in PTFE laminates may be improved with the use of a “clean” peck where the peck depth is set to equal that of the phenolic entry. In this, the entry material will effectively clean the drill bit, retract to clear phenolic debris and cool, and then reenter to drill the hole.

## Hit Count

Hit counts can vary widely and are usually determined by the laminates used. Hit counts of 100-300 hits per bit are typical for ceramic/PTFE constructions. However, in cases where *fastRise™ S* or Specialty *fastRise™* are used with nanomaterials (i.e. *EZ-IO*) or non-ceramic laminates, hit counts of 700-1000 are not uncommon. Hit counts exceeding 2000 hits have been obtained on thick high layer count boards using *EZ-IO* and *fastRise™ S* (see the following photos).

**Note:** *fastRise™ 7* contains fiberglass reinforcement and drill life will be affected accordingly.

100 Hits - *EZ-IO* / *fastRise™ S*

700 Hits - *EZ-IO* / *fastRise™ S*

## Entry / Backer Materials

Rigid entry and exit material is critical in order to remove any debris or deposits from the drill bit. 0.010 – 0.025" (0.25 – 0.60 mm) phenolic entry is acceptable for most applications and 0.030 – 0.050" (0.75 – 1.25 mm) phenolic entry can be used if pressure foot clearance is substantial.

Like the entry, rigid backer is necessary to prevent burring and aid in obtaining hole-wall quality. Thick phenolic is typical and lubricated rigid backers such as SlickBack® from L.C.O.A.® have also been successful.

## Laser Drilling / MicroVias

The lasing of the *fastRise™* part numbers will vary between the different part numbers; please consult the *fastRise™* data sheet or selector guide for details regarding the ideal part numbers. The lack of fiberglass reinforcement produces smoother hole wall plating. Standard *fastRise™* part numbers or *fastRise™ S* part numbers typically yield improved hole-wall quality.

*Laser microvia in FR27-0050-40 as performed by Hughes Circuits*

## HOLE WALL PREPARATION

---

*fastRise™* requires a PTFE activation cycle. *fastRise™* will benefit from a desmear/etchback process performed prior to the PTFE activation.

### Desmear

#### Plasma

If panels have been exposed to moisture, bake the boards at 220°F - 250°F (105°C - 120°C) for one or more hours to drive out moisture. Standard FR4/epoxy desmear processes should then be used. **The desmear plasma time is typically half that of standard FR4/epoxy times because *fastRise™* resin system tends to etch back very quickly.**

#### Permanganate

Permanganate desmear IS NOT RECOMMENDED and has been shown to be very aggressive on *fastRise™* resulting in excessive etchback. This is due to the high silica filler content and thermoset content in the resin system. If permanganate baths must be used for desmear or activation of other materials used in conjunction with *fastRise™*, consult with your Taconic technical service representative for specific process recommendations.

## PTFE Activation

### Plasma

If panels have been exposed to moisture, pre-bake the boards at 220°F - 250°F (105°C - 120°C) for 1 hour. Plasma treat the PTFE resin using 70%/30% Hydrogen/Nitrogen gas mixture. 100% Helium may also suffice. Power settings for the RF-signal generator are typically 60-75% of full rated power for 30-60 minutes, but results may vary. Thick panels or high-aspect ratio holes may require extended plasma cycle times. Thick panels may also benefit from an additional 30 minute O<sub>2</sub> plasma process prior to the PTFE activation plasma.

### Sodium Etch

Sodium Etches (e.g. Fluoroetch) work well with *fastRise™* as well as other Taconic materials. Follow the manufacturer's recommended treatment process. Subsequently, bake for 1 hour at 250° F (120°C) prior to plating to remove moisture that may have been absorbed during the sodium treatment process.

Chlorine can have adverse effects on the sodium treatment. Do not subject exposed sodium etch treated holes to heavily concentrated chlorine-based chemical processes.

## Process Example

The following table is offered by March Plasma as a basic starting point recipe:

<i>Power (kW)</i>	<i>Pressure (mT)</i>	<i>Gases</i>	<i>Gas Ratios</i>	<i>Flow (slm)</i>	<i>Pl Temp (°C)</i>	<i>Time (minutes)</i>	<i>Function</i>
4.5	250	O <sub>2</sub> / N <sub>2</sub>	90 / 10	2.5	90	A/R	Heating
4	250	CF <sub>4</sub> / O <sub>2</sub>	10 / 90	2.5	99	10	Thermoset etch-back
4	250	O <sub>2</sub>	100	2.5	99	5	Removes fluorine and cleans the glass
4.2	250	N <sub>2</sub>	100	2.5	99	30	Activates PTFE. 70/30 H <sub>2</sub> /N <sub>2</sub> Cycle is typically more effective and reliable

## PLATING

---

A robust hole wall preparation process is necessary for a successful deposition plating process due to the PTFE content in the *fastRise™*. Following hole wall preparation, *fastRise™* will accept standard electroless copper or direct metallization plating.

For high-aspect ratios or other difficult to plate applications, a second pass through the electroless process is sometime used to ensure proper hole-wall coverage. It may also be beneficial to run a short duration of electrolyzed copper, rinse etc., then restart the electrolyzed copper from the beginning to expose the hole wall to fresh chemistry.

## IMAGE, DEVELOP, ETCH, STRIP

---

When copper surface preparation is required, chemical cleaning processes are preferred (e.g. microetch); mechanical scrubbing (e.g. pumice scrub) should be avoided due to possible mechanical damage. Although *fastRise™* should be resistant to this damage, typical materials used in conjunction with *fastRise™* may not be. Otherwise, standard processing should be used.

## SOLDER MASK

---

Panels should be clean and dry. No other special treatment is required if the surface has not been mechanically scrubbed.

## SOLDER REFLOW

---

A pre-bake cycle of 2 – 3 hours at 300° F (150°C) is recommended prior to thermal stressing. Longer pre-heat times and minimal cycle times may be advantageous depending on design and processes.

## ROUTING / MILLING

---

*fastRise™* can be successfully machined using standard router bits or end mills. Machine parameters will be driven by the laminates used. In general, rigid phenolic entry and a rigid backer should be used. In some cases, adding paper (white paper or craft paper) between the phenolic and the part allows better conformance to surface topography (e.g. circuits, soldermask, etc.) and may reduce burring. For tight tolerances or superior edge quality, a “rough cut” placed 0.005 – 0.010” (0.1 – 0.2 mm) off the part edge may be run prior to the finish cut at the nominal part edge.
